

SCATTERING RIGIDITY FOR ANALYTIC RIEMANNIAN MANIFOLDS WITH A POSSIBLE MAGNETIC FIELD

PILAR HERREROS AND JAMES VARGO

ABSTRACT. Consider a compact manifold M with boundary ∂M endowed with a Riemannian metric g and a magnetic field Ω . Given a point and direction of entry at the boundary, the scattering relation Σ determines the point and direction of exit of a particle of unit charge, mass, and energy. In this paper we show that a magnetic system $(M, \partial M, g, \Omega)$ that is known to be real-analytic and that satisfies some mild restrictions on conjugate points is uniquely determined up to a natural equivalence by Σ . In the case that the magnetic field Ω is taken to be zero, this gives a new rigidity result in Riemannian geometry that is more general than related results in the literature.

1. AN INTRODUCTION INCLUDING THE RESULTS PROVED

1.1. Magnetic systems and scattering data. Let M be a compact, n -dimensional, Riemannian manifold with boundary ∂M and metric g . Let $\pi : T^*M \rightarrow M$ be the natural projection of the cotangent bundle to M given by $(x, \xi) \mapsto x$. The Hamiltonian flow of the function $H(x, \xi) = \frac{1}{2}|\xi|_g^2$ with respect to the standard symplectic structure of T^*M is the geodesic flow. Given a closed 2-form Ω on M , there is a corresponding *magnetic geodesic flow* which is determined by the same Hamiltonian function, but through the modified symplectic 2-form

$$\omega = dx \wedge d\xi + \pi^*\Omega.$$

The integral curves of this flow, projected to M by π , are the *magnetic geodesics*. The level sets of H are preserved along the flow and that implies that the magnetic geodesics have constant speed. In this paper, we shall restrict our attention to the energy level $H = 1/2$, the unit co-sphere bundle S^*M . The isomorphism $T^*M \rightarrow TM$ induced by the metric g transforms the magnetic flow to a flow on SM , the sphere bundle in TM . Let $\mathcal{X}$ and $\mathcal{X}_\mu$ denote the vector fields on SM generating the standard geodesic flow and magnetic geodesic flow, respectively. They are related by the equation

$$\mathcal{X}_\mu(x, v) = \mathcal{X}(x, v) + Y(x)v,$$

where Y is an antisymmetric $(1, 1)$ tensor on M satisfying

$$\langle Y(x)v, w \rangle_g = \Omega(v, w).$$

Let $\Phi^t : SM \rightarrow SM$ denote the magnetic geodesic flow. Given a pair $(x, \theta) \in SM$, let $\gamma_{x, \theta}$ or $\gamma_{x, \theta}(t)$ denote the magnetic geodesic with initial point and vector (x, θ) . We also use the magnetic exponential map

$$\exp^\mu : TM \rightarrow M,$$

defined by $\exp_x^\mu(t\theta) = \gamma_{x, \theta}(t)$ for unit length θ . This map is C^1 everywhere and smooth away from $\theta = 0$.

Definition 1. A 4-tuple $(M, \partial M, g, \Omega)$ is called a **magnetic system**. Two such systems $(M_i, \partial M_i, g_i, \Omega_i)$, $i = 1, 2$ with the same boundary $\partial M_1 = \partial M_2$ are said to be **equivalent** if there exists a diffeomorphism $\varphi : M_1 \rightarrow M_2$ such that:

$$\varphi^* g_2 = g_1, \quad \varphi^* \Omega_2 = \Omega_1, \quad \varphi|_{\partial M} = id.$$

The diffeomorphism φ is called a **magnetic equivalence**.

In this paper, the term analytic shall mean real-analytic. We define a magnetic system $(M, \partial M, g, \Omega)$ to be *analytic* if there exists a magnetic system $(M', \partial M', g', \Omega')$ with M' a real-analytic open manifold containing M such that:

- (i) $g'|_M = g$ and $\Omega'|_M = \Omega$,
- (ii) g' and Ω' are real-analytic on M' ,
- (iii) ∂M is a real-analytic submanifold of M' .

The extensions (g', Ω') are uniquely determined from (g, Ω) by analytic continuation and shall henceforth be denoted without the prime. That is, (g, Ω) shall denote its own extension to M' .

The *scattering magnetic rigidity question* is whether the equivalence class of a magnetic system is determined by the scattering of its magnetic geodesics. Given a point of entry $x \in \partial M$ and an initial direction $\theta \in S_x M$, the scattering data tells all future points of contact $\gamma_{x,\theta} \cap \partial M$ as well as the directions of motion at those points. More precisely:

Definition 2. A pair of vectors $(v, w) \in \partial SM \times \partial SM$ belongs to the **scattering relation** Σ if for some $t \geq 0$, $w = \Phi^t(v)$.

After properly defining all the terms and introducing some minor restrictions on conjugate points, it is shown that two analytic magnetic systems are equivalent if they have the same scattering data.

This problem descends from the *boundary rigidity problem* in which one seeks to recover a metric g up to isometry from the boundary distance function $\rho_g : \partial M \times \partial M \rightarrow \mathbb{R}$, defined by:

$$\rho_g(x, y) = \inf\{\text{length}(\gamma) : \gamma \subset M \text{ is a curve joining } x \text{ to } y\}.$$

A particular Riemannian manifold with boundary $(M, \partial M, g)$ is called *boundary rigid* if all other such manifolds with the same boundary distance function are in the same isometry class. The known examples of manifolds that are not boundary rigid either have trapped geodesics (geodesics that never leave the manifold) or conjugate points. The most general class of manifolds conjectured to be boundary rigid are those with the SGM property. This property is detectable from the boundary and is equivalent to the two conditions that there are no trapped geodesics and that all geodesic segments are strong length minimizers [C1]. SGM manifolds homeomorphic to a ball with a strictly convex boundary are called *simple*. It has been conjectured that all simple manifolds are boundary rigid (e.g. [Mi]), but so far, such a general statement has only been confirmed in dimension 2 in work by Pestov and Uhlmann [PU]. In higher dimensions, Gromov showed that subregions of Euclidean space are boundary rigid [Gr]. Other spaces known to be boundary rigid are subregions of boundary rigid spaces, subregions of a hemisphere [Mi], simple symmetric spaces of negative curvature [BCG], and SGM subregions of spaces with a parallel vector field [CK]. Recently, it was shown by Burago and Ivanov that metrics sufficiently close in the C^∞ topology to the Euclidean metric on a convex

domain are boundary rigid [BI]. The last result implies, for example, that for any point on any Riemannian manifold, a sufficiently small neighborhood of that point is boundary rigid.

In applications, this problem is called travel time tomography and goes back at least as far as the early 20th century, when it was proposed to measure seismic waves to reconstruct an image of the inner structure of the earth. Besides being used widely by geophysicists, travel time tomography is used by oceanographers and atmospheric scientists, and has potential applications in medical imaging. In some applications, it is natural to assume that the metric is isotropic; that is, conformal to the Euclidean. For metrics in a given conformal class, uniqueness was first shown for simple metrics by Mukhometov [Mu] and later by Croke for SGM metrics [C1].

The SGM and simplicity conditions are restrictive geometric conditions which are not typically satisfied in applications. In more general circumstances, one can instead consider the lens data, which consists of the scattering data together with the travel times of the geodesics. It was shown by Michel that the lens data is equivalent to the boundary distance function for simple manifolds [Mi]. If trapped geodesics are allowed, then counterexamples to lens rigidity exist [CK]. Croke showed that if a manifold is lens rigid, then so is a finite quotient of that manifold [C2]. In [V] lens rigidity was shown if the metrics are a priori assumed to be real analytic. Stefanov and Uhlmann proved lens rigidity for metrics that are a priori known to be close to a given base metric taken from a set of generic metrics including the real analytic ones [SU2].

The magnetic rigidity problem is related to the question of whether there are more general families of curves whose defining parameters can be recovered from boundary measurements. Magnetic geodesics and the magnetic flow were first considered by V.I. Arnold [Ar1] and D.V. Anosov and Y.G. Sinai [AS]. Since then it has been studied from several approaches (e.g. [CMP, Gi, Grog, NT, PP]) and their boundary rigidity, in particular, has been studied in [DPSU, He].

One motivation for magnetic boundary rigidity is that it has potential applications to problems of geometry. In the case of surfaces, magnetic geodesics are related to the study of curves of constant geodesic curvature. This relation has been used to study the existence of closed curves with prescribed geodesic curvature (see e.g. [Ar2, Le, Sch]). Magnetic boundary rigidity was used in [He] to show that a surface of constant curvature cannot be modified in a small region while keeping all the curves of a fixed constant geodesic curvature closed.

Let $\iota : \partial M \hookrightarrow M$ be inclusion. Since a magnetic equivalence fixes the points of ∂M , the pullbacks ι^*g and $\iota^*\Omega$ are preserved. However the scattering relation Σ is not preserved because its definition depends on the set ∂SM which is defined through $g|_{\partial M}$. For this reason we reparametrize Σ through the natural diffeomorphism

$$\Lambda : \partial SM \rightarrow \partial \tilde{S}M = \{(w, r) \in T\partial M \times \mathbb{R} : |w|_g^2 + r^2 = 1\}.$$

Λ is given by $v \mapsto (v^T, \langle v, \nu \rangle_g)$, where v^T denotes the orthogonal projection of $v \in \partial SM$ to $T\partial M$, and ν denotes the inward-pointing unit normal vector. The reparametrized scattering relation, $\tilde{\Sigma} \subset \partial \tilde{S}M \times \partial \tilde{S}M$, is defined to be $\tilde{\Sigma} = (\Lambda \times \Lambda)(\Sigma)$. Given an equivalence class of magnetic systems $\{(M, \partial M, g, \Omega)\}$, we shall call $(\partial M, \iota^*g, \iota^*\Omega, \tilde{\Sigma})$ the associated *scattering data*.

An equivalent way of parametrizing the scattering data is given through *boundary normal coordinates*. Given $x_0 \in \partial M$, there exists a neighborhood $N \subset \partial M$ of x_0 and a number $\epsilon > 0$ such that the map

$$\exp_\nu : N \times (-\epsilon, \epsilon) \rightarrow M'$$

given by $\exp_\nu(x', x^n) = \exp_{x'}(x^n \nu)$ is an injective immersion. Here $\exp$ denotes the exponential map corresponding to the Riemannian metric g , not the magnetic exponential $\exp^\mu$. Moreover, if $x^\alpha : 1 \leq \alpha \leq n-1$ are local coordinates for ∂M , then the metric tensor has the form

$$g = g_{\alpha\beta}(x) dx^\alpha dx^\beta + (dx^n)^2.$$

(x', x^n) , as local coordinates for M near x_0 are called *boundary normal coordinates*, or *semigeodesic coordinates*. Note that the curves given by $x' = \text{const}$ are geodesics (not magnetic geodesics) of (M, g) normal to ∂M .

Since ∂M is compact, it is possible to extend the boundary normal coordinates to a collared neighborhood of the entire boundary. Indeed, if ϵ is sufficiently small, then we obtain a diffeomorphism

$$(1.1) \quad \exp_\nu : \partial M \times (-\epsilon, \epsilon) \rightarrow V,$$

where $V \subset M'$ consists of the points whose distance to ∂M is less than ϵ . For a detailed proof, see [V]. It shall be convenient to set

$$M' = M \cup V.$$

Finally, when discussing two magnetic systems with the same boundary, we shall assume that the value of ϵ is chosen sufficiently small so that (1.1) is a valid diffeomorphism for both.

Note that the mapping Λ is equal to the pullback of vectors at the boundary by $\exp_\nu$.

$$\Lambda = \exp_\nu^*|_{\partial SM}.$$

Definition 3. $(M, \partial M, g, \Omega)$ is called **non-trapping** if for all $(x, \theta) \in SM$, there exist $T_- < 0$ and $T_+ > 0$ such that $\gamma_{x, \theta}(T_\pm) \in M' \setminus M$; that is, every magnetic geodesic must eventually leave M in both directions.

In this paper, we shall assume that all magnetic systems are non-trapping. Let $v = (x, \theta) \in \partial SM$, and let $\ell(v) = T$ be defined by

$$T = \inf \{t \geq 0 : \gamma_v(t) \notin M\}.$$

Then $\gamma_v(T)$ and $\gamma'_v(T)$ are respectively called the terminal point and direction of γ_v in M . The mapping

$$\ell : \partial SM \rightarrow \mathbb{R}$$

is called the *travel time map* of M . The corresponding map $\tilde{\ell} : \partial \tilde{SM} \rightarrow \mathbb{R}$ given by $\tilde{\ell} = \ell \circ \Lambda^{-1}$ is called the *travel time data* of the equivalence class of $(M, \partial M, g, \Omega)$.

Definition 4. We say that v satisfies **condition A** if there are no points in $\partial M \cap \{\gamma_v(t) : 0 \leq t \leq T\}$ that are conjugate to x along γ_v . In this paper, conjugate shall always mean with respect to the magnetic flow. We shall say that an analytic magnetic system $(M, \partial M, g, \Omega)$ satisfies **condition $\hat{A}$** if there exists at least one vector in each connected component of ∂SM that satisfies condition A.

Let $\mathcal{G}$ be the collection of magnetic geodesic segments in M whose endpoints lie in ∂M and do not intersect ∂M at any other point. Let $\gamma \in \mathcal{G}$ be an element with initial vector $v \in SM$, travel time T , and final point $y = \gamma(T)$.

Definition 5. We say that γ satisfies **condition B** if there are no points on γ that are conjugate of order $n - 1$ to y . We shall say that an analytic magnetic system $(M, \partial M, g, \Omega)$ satisfies **condition $\hat{B}$** if the set of magnetic geodesic segments in $\mathcal{G}$ satisfying condition B is dense in $\mathcal{G}$.

Recall that if x and y belong to M and $y = \exp_x^\mu(v)$, then x and y are conjugate if $d_v \exp_x^\mu(v)$ is singular. The order, or multiplicity, of conjugacy is equal to the dimension of the kernel with $n - 1$ being the largest possible. For example, two antipodal points on S^n (with $\Omega = 0$) are conjugate of order $n - 1$.

Lemma 1. Condition A is open in ∂SM . Condition B is open in $\mathcal{G}$.

Proof. The openness of condition B is clear. Let $v_0 \in \partial SM$ satisfy condition A. Let $K = \gamma_{v_0} \cap \partial M$. By compactness, for any open neighborhood N of K , there exists an open $\tilde{U}$ about v_0 in SM' such that for all $v \in \tilde{U}$, $\gamma_v \cap \partial M \subset N$.

Since x_0 , the basepoint of v_0 , is not conjugate to any point of K , we may choose N and the corresponding neighborhood $\tilde{U}$ sufficiently small so that for each $v \in \tilde{U}$, its basepoint x will not be conjugate to any point of $\gamma_v \cap N$. But since $\gamma_v \cap \partial M \subset N$, we find that x will not be conjugate to any point of $\gamma_v \cap \partial M$. $\square$

Theorem 1. Let $(M_i, \partial M, g_i, \Omega_i)$, $i = 1, 2$ be two non-trapping, analytic magnetic systems satisfying condition $\hat{B}$ and assume that $(M_1, \partial M, g_1, \Omega_1)$ satisfies condition $\hat{A}$. Then if the two systems have the same scattering data, they must be equivalent.

The first step of the proof is to show that the mapping $\varphi_0 : V_1 \rightarrow V_2$ given by

$$(1.2) \quad \varphi_0 = \exp_{\nu_2} \circ \exp_{\nu_1}^{-1}$$

is a magnetic equivalence fixing the points of ∂M . To do this, we must use condition A to show that the coefficients of (g, Ω) are uniquely determined by the scattering data in boundary normal coordinates. The main step is to prove the following theorem.

Theorem 2. Let $(M_i, \partial M, g_i, \Omega_i)$, $i = 1, 2$ be non-trapping, analytic magnetic systems with the same scattering data, and assume that $v_0 = (x_0, \theta_0) \in S\partial M$ satisfies condition A in M_1 . Then at the point x_0 , the coefficients of (g_1, Ω_1) and (g_2, Ω_2) , expressed in boundary normal coordinates, have the same jets at x_0 . That is, their values at x_0 are the same, and the values of all their derivatives of all orders at x_0 are the same.

This theorem is a direct generalization of a result by Plamen Stefanov and Gunther Uhlmann for Riemannian metrics (with no magnetic fields). We extend their result by allowing magnetic fields and by only assuming the scattering data and no magnetic analog of length data. In order to generalize the proof, some extra condition is needed for the case when the magnetic geodesics near γ_{v_0} are short. For this paper the convenient extra assumption is to assume that the system be analytic. However it should be noted that this is not at all an essential condition and could be easily be replaced by a certain weak convexity condition. See the remark after the proof for details.

A similar theorem was proved for magnetic systems by [DPSU] in which they assume strict convexity of the boundary with respect to magnetic geodesics and take a certain action function as the given data. We use a similar action function to prove this theorem, but do not otherwise use the same techniques since we allow for the possibility that γ_{v_0} be a long magnetic geodesic. Rather we follow Stefanov and Uhlmann's proof, the idea of which is to consider a function $\rho(x, y)$ which gives travel times between pairs of points. Fixing y , the function satisfies the eikonal equation:

$$g^{ij}(x)(\partial_{x_i}\rho)(\partial_{x_j}\rho) = 1.$$

Using this equation, the scattering data tells us just enough about the derivatives of ρ to reconstruct the jet of g . The proof here follows the same program, but with modifications to account for magnetic fields and the lack of explicit travel time data. We construct an analogous action function $\rho(x, y)$ which satisfies an eikonal-type equation (equation (2.4)) whose coefficients come from g and Ω . We then use the scattering data to infer enough information about the derivatives of ρ to recover the jets of g and Ω .

The next step in the proof of Theorem 1 is the proof of the following theorem.

Theorem 3. *Let $(M_i, \partial M, g_i, \Omega_i)$, $i = 1, 2$ be two non-trapping, analytic magnetic systems that satisfy condition B and have the same scattering data. If $\varphi_0 : V_1 \rightarrow V_2$ is an equivalence, then corresponding elements of $\mathcal{G}_1$ and $\mathcal{G}_2$ have the same travel times. In particular, the two systems have the same travel time data $\tilde{\ell}$.*

Elements of $\mathcal{G}_1$ and $\mathcal{G}_2$ are corresponding if their initial and final vectors are related by φ_0 . The next theorem finishes the proof of 1.

Theorem 4. *Let $(M_i, \partial M, g_i, \Omega_i)$, $i = 1, 2$ be two non-trapping, analytic magnetic systems with the same scattering and travel time data. If $\varphi_0 : V_1 \rightarrow V_2$ is an equivalence, then φ_0 extends to an equivalence $\varphi : M'_1 \rightarrow M'_2$.*

2. THEOREM 2: RECOVERY OF THE MAGNETIC SYSTEM IN A NEIGHBORHOOD OF THE BOUNDARY

2.1. Defining an action function on magnetic geodesic segments. The first step shall be to construct an action function which serves the role of the travel time function used by Stefanov and Uhlmann. Subscripts shall be omitted as long as all statements apply equally to both manifolds. We consider our magnetic system to be extended to an open manifold M' containing M . Let $\gamma = \{\gamma(t) : 0 \leq t \leq T\}$ be a magnetic geodesic segment in M' . For our proof, we shall need a 1-form ζ , defined in a neighborhood of γ , satisfying $d\zeta = \Omega$. By the Poincaré lemma, such a 1-form exists if γ has no self-intersections. If γ does intersect itself, then we circumvent the topological problem through the construction described in the following paragraphs.

Let $\tilde{\gamma}$ denote the segment in $\mathbb{R}^n$ given by

$$\tilde{\gamma}(t) = (0, \dots, 0, t) \quad \text{for } 0 \leq t \leq T.$$

Then there exists a neighborhood $U \subset \mathbb{R}^n$ of $\tilde{\gamma}$ and an immersion $\psi : U \rightarrow M'$ that satisfies $\psi(0, t) = \psi \circ \tilde{\gamma}(t) = \gamma(t)$. For example, we can construct such a map in the following way. Extend γ to an open interval containing $[0, T]$ and choose vectors $X_i(t)$ along $\gamma(t)$ such that $(X_1(t), \dots, X_{n-1}(t), \gamma'(t))$ are linearly independent for

all t . Then define

$$\psi(x^1, \dots, x^{n-1}, x^n) = \exp_{\gamma(x^n)} \left(\sum_{i=1}^{n-1} x^i X_i(x^n) \right).$$

The topology of U is trivial so by the Poincaré lemma, there exists ζ such that $d\zeta = \psi^*\Omega$. We call ζ a *magnetic potential* in a neighborhood of γ .

Let $\tilde{x}$ be coordinates for U , and $(\tilde{x}, \tilde{\xi})$ the corresponding natural coordinates for T^*U . Using ψ we can pull back structures from M' to U . In particular, we obtain an exact symplectic form

$$\tilde{\omega} = d\tilde{x} \wedge d\tilde{\xi} + \psi^*\Omega = -d(\tilde{\xi} d\tilde{x} - \zeta)$$

and a Hamiltonian function $\tilde{H} = \frac{1}{2}|\tilde{\xi}|_g^2$. Together, these generate Hamiltonian curves whose projections to U are the magnetic geodesics of the magnetic system $(U, \psi^*g, \psi^*\Omega)$.

We parametrize the magnetic geodesic segments in M' near γ by their initial vector $v \in SM'$ and their length τ .

$$(v, \tau) \mapsto \gamma_{v, \tau} = \{\gamma_v(t) : 0 \leq t \leq \tau\}.$$

Let (v_0, τ_0) correspond to the original segment γ about which ζ was constructed. For (v, τ) in some neighborhood $\mathcal{M}$ about (v_0, τ_0) , the magnetic geodesic segments $\gamma_{v, \tau}$ in M' can be uniquely pulled back via ψ to magnetic geodesic segments $\tilde{\gamma}_{v, \tau}$ in U . Let $\tilde{c}_{v, \tau}$ denote the corresponding Hamiltonian curve in T^*U .

Letting $\mathcal{N}$ denote the neighborhood of magnetic geodesic segments

$$\mathcal{N} = \{\gamma_{v, \tau} : (v, \tau) \in \mathcal{M}\},$$

we define the action functional $\mathbf{A}_\zeta : \mathcal{N} \rightarrow \mathbb{R}$ by

$$\mathbf{A}_\zeta[\gamma_{\mathbf{v}, \tau}] = \tau - \int_{\tilde{\gamma}_{\mathbf{v}, \tau}} \zeta.$$

In the case that Ω is exact, ζ can be defined on all of M' so that $\mathbf{A}_\zeta$ is well-defined for all magnetic geodesics. But in general this is not possible so the action can only be defined near one fixed curve. In either case, $\mathbf{A}_\zeta$ depends on the choice of ζ which is not uniquely determined by the magnetic system.

Proposition 1.

$$\mathbf{A}_\zeta[\gamma_{\mathbf{v}, \tau}] = \int_{\tilde{c}_{\mathbf{v}, \tau}} (\tilde{\xi} d\tilde{\mathbf{x}} - \pi^*\zeta)$$

Proof. Along the curve $\tilde{c}_{v, \tau}$, we have $\tilde{\xi} d\tilde{x} = |\tilde{\xi}|_g^2 dt = dt$. Therefore, noting that $\tilde{\gamma}_v(t) = \pi \circ \tilde{c}_v(t)$, the integral on the right is equal to

$$\tau - \int_{\tilde{c}_{v, \tau}} \pi^*\zeta = \tau - \int_{\tilde{\gamma}_{v, \tau}} \zeta.$$

□

2.2. The first variation of $\mathbf{A}_\zeta$. Let $\gamma_s(t) : -\epsilon \leq s \leq \epsilon, 0 \leq t \leq \tau_s$ be a smooth 1-parameter family of unit-speed magnetic geodesics in $\mathcal{N}$. Correspondingly, there is a smooth 1-parameter family of curves $\tilde{c}_s(t)$ in T^*U , and by the lemma, we have

$$\varphi(s) = \mathbf{A}_\zeta[\gamma_s] = \int_{\tilde{c}_s} (\tilde{\xi} d\tilde{x} - \pi^* \zeta).$$

Let $a(s)$ be the curve $\tilde{c}_s(0)$ and $b(s)$ be the curve $\tilde{c}_s(\tau_s)$. Now let $0 < |h| < \epsilon$, and consider the surface σ with parametrization $(s, t) \mapsto \tilde{c}_s(t) : 0 \leq s \leq h, 0 \leq t \leq \tau_s$.

According to Stokes' theorem,

$$\left(\int_{\tilde{c}_0} + \int_b - \int_{\tilde{c}_h} - \int_a \right) (\tilde{\xi} d\tilde{x} - \pi^* \zeta) = \int_\sigma (d\tilde{\xi} \wedge d\tilde{x} - \pi^* \Omega).$$

It follows that

$$\frac{\varphi(h) - \varphi(0)}{h} = \frac{1}{h} \left(\int_b - \int_a \right) (\tilde{\xi} d\tilde{x} - \pi^* \zeta) - \frac{1}{h} \int_\sigma (d\tilde{\xi} \wedge d\tilde{x} - \pi^* \Omega).$$

The surface integral on the right-hand side is equal to 0. To show this we note that the 2-form being integrated is $-\tilde{\omega}$, the symplectic form. We also note that the Hamiltonian vector field $X_{\tilde{H}} = \frac{\partial}{\partial t} c_s(t)$ lies tangent to σ . By definition,

$$\tilde{\omega}(X_{\tilde{H}}, \cdot) = d\tilde{H}.$$

Since σ is contained in the level surface $\tilde{H} = 1/2$, we conclude that the pull back of $\tilde{\omega}$ to σ must be 0. Hence we obtain

$$\frac{\varphi(h) - \varphi(0)}{h} = \frac{1}{h} \left(\int_b - \int_a \right) (\tilde{\xi} d\tilde{x} - \pi^* \zeta).$$

Taking the limit as $h \rightarrow 0$, we find

$$\varphi'(0) = (\tilde{\xi} d\tilde{x} - \pi^* \zeta)|_{a'(0)}^{b'(0)}$$

$\tilde{c}_s(t) = (\tilde{\gamma}_s(t), \tilde{\xi}_s(t))$ where $\tilde{\xi}_s(t)$ is the covector corresponding to $\partial_t \tilde{\gamma}_s(t)$ by g . Therefore

$$(2.1) \quad \varphi'(0) = [\langle \partial_t \tilde{\gamma}_0, \cdot \rangle_g - \zeta]|_{\pi_* a'(0)}^{\pi_* b'(0)}$$

In terms of the family of magnetic geodesics $\{\tilde{\gamma}_s(t)\}_s$, $\pi_* a'(0)$ and $\pi_* b'(0)$ are just the variations in the initial and terminal point, respectively, of the curves.

Now suppose that $\gamma = \gamma_{v_0, \tau_0}$ has endpoints x_0 and y_0 which are not conjugate to each other. Then for (x, y) in a sufficiently small neighborhood around (x_0, y_0) , there exists a magnetic geodesic $\gamma_{x,y}$ joining x to y which is smoothly dependent on x and y . Let $\theta = \theta_{x,y} \in T_x M'$ be its initial vector and define the smooth function

$$\rho(x, y) = \mathbf{A}_\zeta[\gamma_{x,y}].$$

Let $w \in T_x M'$. If we fix y and take the differential of ρ with respect to x , then by (2.1), we obtain:

$$(2.2) \quad \langle d_x \rho, w \rangle = -\langle \theta, w \rangle_g + \langle \zeta, w \rangle$$

Solving for θ , we find

$$(2.3) \quad -\langle \theta, \cdot \rangle_g = d_x \rho - \zeta.$$

In particular since γ is a unit-speed curve, θ has unit length, so

$$|d_x \rho - \zeta|_g^2 = 1.$$

Written another way,

$$(2.4) \quad g^{ij}(x)(\partial_{x^i}\rho - \zeta_i(x))(\partial_{x^j}\rho - \zeta_j(x)) = 1.$$

This is the eikonal-type equation that we need.

2.3. Choosing compatible magnetic potentials. Now we consider again our two manifolds M_1 and M_2 with their respective metrics and magnetic fields and extensions M'_1 and M'_2 . We let $v_0 = (x_0, \theta_0) \in S\partial M$ be a vector satisfying the hypothesis of the theorem. For each $i = 1, 2$, let $\gamma_i \subset M'_i$ be the magnetic geodesic with initial vector v_0 , and let ζ_i be an arbitrarily chosen magnetic potential in a neighborhood of γ_i . The next lemma shows that the two potentials can be made compatible with each other in a certain sense. Recall that (x', x^n) denote boundary normal coordinates near x_0 .

Lemma 2. *If the two magnetic systems have the same scattering data, then there exist magnetic potentials ζ_1, ζ_2 defined in neighborhoods of γ_1 and γ_2 respectively which satisfy*

$$\iota_1^*\zeta_1 = \iota_2^*\zeta_2, \quad \text{and}$$

$$\langle \zeta_1, \partial_{x^n} \rangle = \langle \zeta_2, \partial_{x^n} \rangle,$$

in a neighborhood of the point x_0 .

Proof. Starting with arbitrary ζ_1 and ζ_2 , note that

$$d(\iota_1^*\zeta_1 - \iota_2^*\zeta_2) = \iota_1^*\Omega_1 - \iota_2^*\Omega_2 = 0.$$

Therefore, there exists a smooth function f_0 defined in a neighborhood of x_0 in ∂M such that

$$\iota_1^*\zeta_1 - \iota_2^*\zeta_2 = df_0.$$

We extend f_0 in a neighborhood of ∂M according to the first order PDE

$$\begin{aligned} \partial_{x^n} f &= \langle \zeta_1, \partial_{x^n} \rangle - \langle \zeta_2, \partial_{x^n} \rangle, \\ f|_{\partial M} &= f_0. \end{aligned}$$

Away from the boundary we apply a cutoff function so that f is well-defined over a neighborhood of γ_1 . Letting $\zeta'_1 = \zeta_1 + df$, we find that ζ'_1 and ζ_2 satisfy the requisite conditions. $\square$

2.4. Proof of Theorem 2. For the remainder of the proof, subscripts distinguishing the two manifolds shall be omitted. We are given a magnetic system $(M, \partial M, g, \Omega)$ with known scattering data $(\partial M, \iota^*g, \iota^*\Omega, \tilde{\Sigma})$ and extension $(M', \partial M, g, \Omega)$. We will be working in boundary normal coordinates near a point $x_0 \in \partial M$. In these coordinates, we may regard $g|_{\partial M}$ as known since ι^*g is included in the scattering data.

We start with a lemma. Let $v_0 \in \partial SM$ be a unit vector at the boundary, and let ζ be a magnetic potential in a neighborhood of γ_{v_0} . Let y_0 be a point on $\gamma_{v_0} \cap \partial M$ with $y_0 \neq x_0$ and assume that x_0 and y_0 are not conjugate along γ_{v_0} . Then there exist respective neighborhoods V, W about x_0, y_0 in the extended manifold M' such that for any $x \in V, y \in W$, there is a magnetic geodesic $\gamma_{x,y}$ connecting them. It depends smoothly on the endpoints and is equal to $\gamma_{v_0}|_{[x_0, y_0]}$ if $(x, y) = (x_0, y_0)$. As discussed above, the function $\rho(x, y) = \mathbf{A}_\zeta[\gamma_{xy}]$ is smooth with derivative given in equation (2.2).

According to lemma 2, we may regard $\iota^*\zeta$ as known data. What's more, we may regard $\zeta(\partial_{x^n})$ as known in a neighborhood of x_0 even off the boundary. In particular, $\iota^*\zeta$ and $\zeta(\partial_{x^n})|_{\partial M}$ together give us $\zeta|_{\partial M}$ in boundary normal coordinates. If we let $\hat{\zeta}$ denote the vector field corresponding to ζ via g , then that is also known on ∂M . What we need for the theorem is the full jet of g and ζ at ∂M . But since we already know g and ζ on ∂M , what remains is to recover their derivatives in the normal direction. That is, we need:

$$\partial_{x^n}^k g|_{\partial M}, \quad \partial_{x^n}^k \zeta|_{\partial M}, \quad k = 1, 2, \dots$$

Actually, what we shall get are these normal derivatives on a half-neighborhood of x_0 in ∂M . This is enough to apply tangential derivatives to get the full jets at x_0 .

Lemma 3. *Let $v_0 \in \partial SM$ be a unit vector over the point $x_0 \in \partial M$ which points strictly inwards, i.e. $\langle v_0, \nu \rangle_g > 0$. Let y_0 be the first point of intersection between γ_{v_0} and ∂M . Then if x_0 and y_0 are not conjugate, the scattering data uniquely determine $d_x \rho(x, y_0)$ for $x \in \partial M$ sufficiently close to x_0 .*

Proof. The existence of y_0 is guaranteed by the fact that v_0 is inward pointing and that our systems are non-trapping. Let $\tau > 0$ denote the travel time of the magnetic geodesic from x_0 to y_0 . Then $\gamma_{v_0}(\tau) = y_0$. Let $w_0 = \gamma'_{v_0}(\tau)$, the vector tangent to the curve at y_0 . It should be noted that both y_0 and w_0 are determined by the scattering relation. For small $\epsilon > 0$, let

$$C_\epsilon = \{w \in S_{y_0}M : \langle w, w_0 \rangle_g > 1 - \epsilon, \langle w, \nu \rangle_g < 0\}.$$

Since y_0 is the first point of intersection of γ_{v_0} with ∂M , it is clear that $\langle w_0, \nu \rangle_g \leq 0$ with equality if and only if w_0 is tangent to ∂M . Therefore, C_ϵ is either an open cone or a half-open cone about w_0 , depending on whether w_0 is tangent to ∂M . Note that in the case that it is only half-open, w_0 is a limit point, but not actually a member of C_ϵ .

The elements of C_ϵ are strictly outward pointing, so they are terminal vectors of magnetic geodesics. Since v_0 is transverse to ∂M , we see that $\{(v, w) \in \Sigma : w \in C_\epsilon\}$ gives a one-to-one correspondence between vectors v near v_0 with vectors $w \in C_\epsilon$. Let κ denote the composition of the corresponding maps

$$\begin{aligned} C_\epsilon &\rightarrow \partial SM \rightarrow \partial M, \\ w &\mapsto v \mapsto \pi(v), \end{aligned}$$

where $\pi(v)$ is projection to the base point. Since x_0 and y_0 are not conjugate, κ is a diffeomorphism. Also, it is determined by the scattering data. Its image, which we will denote by $\mathcal{H}$, is either a half-neighborhood or full neighborhood of x_0 depending on whether C_ϵ is a half-cone or full cone about w_0 .

The function $\rho(x, y_0)$ is well-defined for $x \in M'$ in an open neighborhood about x_0 . We may assume that $\mathcal{H}$ is taken small enough to lie inside this neighborhood. Then from the previous discussion, we see that for $x \in \mathcal{H} \subset \partial M$, there exists a unique vector $v_x \in S_x M$, close to v_0 , such that y lies on γ_{v_x} . Indeed v_x is a point in the image of the map $C_\epsilon \rightarrow \partial SM$. By equation (2.2),

$$\nabla_x \rho(x, y_0) = \hat{\zeta}_x - v_x.$$

The terms on the right are uniquely determined, since v_x is known from the scattering data, and $\hat{\zeta}$ is known on ∂M . Therefore, since $g|_{\partial M}$ is known, we find $d_x \rho(x, y_0)$ at points $x \in \mathcal{H}$ by lowering the index of $\nabla_x \rho(x, y_0)$. $\square$

Proof of Theorem 2. Let $v_0 \in S\partial M$ satisfy condition A. By lemma 1, the vector

$$(2.5) \quad v_s(x_0) = \cos(s)v_0 + \sin(s)\nu$$

will also satisfy condition A for sufficiently small $s \geq 0$. We let y_s denote the first point of intersection between $\gamma_{v_s(x_0)}$ and ∂M , and we let w_s be the tangent to the magnetic geodesic at y_s . By compactness, there is a sequence $s_m \rightarrow 0$ such that (y_{s_m}, w_{s_m}) converges to a vector (y_*, w_*) tangent to γ_{v_0} and lying over a point of ∂M . We split the proof of the theorem into the two possible cases that $w_* = v_0$ or $w_* \neq v_0$ which correspond to whether the length of the magnetic geodesic γ_{v_0} from x_0 to y_* has length 0 or not.

Case I: $w_* \neq v_0$.

Let $\rho_m(x)$ denote the function $\rho(x, y_{s_m})$. Let $\mathcal{H}_m$ be the corresponding (half)-neighborhood of x_0 referred to in the previous lemma. For $x \in M'$ nearby x_0 , let $v_{s_m}(x)$ be the initial vector of the magnetic geodesic connecting x to y_{s_m} , and let $\hat{v}_{s_m}$ be the corresponding covector.

$$\begin{aligned} v_{s_m}(x) &= \hat{\zeta}_x - \nabla_x \rho_m(x) \\ \hat{v}_{s_m}(x) &= \zeta_x - d_x \rho_m(x). \end{aligned}$$

For $x \in \mathcal{H}_m$, both $v_{s_m}(x)$ and $\hat{v}_{s_m}(x)$ are uniquely determined by the scattering data.

We make the following conventions of notation. Near x_0 our boundary normal coordinates shall be

$$\{(x^\alpha, x^n) : \alpha = 1, \dots, n-1\}.$$

A subscript or superscript of α or n shall mean the corresponding tensor component: e.g. $\partial_n = \partial_{x^n}$, $\zeta_\alpha = \zeta(\partial_\alpha)$, etc. By equation (2.4), we have in boundary normal coordinates:

$$g^{\alpha\beta}(\zeta_\alpha - \partial_\alpha \rho_m)(\zeta_\beta - \partial_\beta \rho_m) + (\theta_n - \partial_n \rho_m)^2 = 1,$$

or

$$g^{\alpha\beta}(\hat{v}_{s_m})_\alpha (\hat{v}_{s_m})_\beta + (\hat{v}_{s_m})_n^2 = 1.$$

This equation is valid for all x which are sufficiently close to x_0 in the extended manifold M' . For $x \in \mathcal{H}_m$, the coefficients of the equation are known. We shall find the normal derivatives of g and ζ by successively applying ∂_n to this equation and solving for all unknown terms at each step.

For the first step, we apply ∂_n and obtain the equation:

$$(2.6) \quad (\partial_n g^{\alpha\beta})(\zeta_\alpha - \partial_\alpha \rho_m)(\zeta_\beta - \partial_\beta \rho_m) + 2g^{\alpha\beta}(\partial_n \zeta_\alpha - \partial_n \partial_\alpha \rho_m)(\zeta_\beta - \partial_\beta \rho_m) \\ + 2(\zeta_n - \partial_n \rho_m)(\partial_n \zeta_n - \partial_n^2 \rho_m) = 0.$$

Splitting the second term and rearranging yields

$$(2.7) \quad (\partial_n g^{\alpha\beta})(\hat{v}_{s_m})_\alpha (\hat{v}_{s_m})_\beta + 2(g^{\alpha\beta} \partial_n \zeta_\alpha)(\hat{v}_{s_m})_\beta = \\ 2g^{\alpha\beta}(\hat{v}_{s_m})_\beta \partial_n \partial_\alpha \rho_m - 2(\hat{v}_{s_m})_n (\partial_n \zeta_n - \partial_n^2 \rho_m).$$

Next, we let $m \rightarrow \infty$. On the left side we obtain:

$$(\partial_n g^{\alpha\beta})(\hat{v}_0)_\alpha (\hat{v}_0)_\beta + 2(g^{\alpha\beta} \partial_n \zeta_\alpha)(\hat{v}_0)_\beta.$$

For fixed $x = x_0$ and variable $\hat{v} \in S_{x_0}^* \partial M$, this expression can be regarded as a non-homogeneous quadratic function $F(\hat{v})$. We wish to show that at $x = x_0$, the

value $F(\hat{v}_0)$ is uniquely determined. The fact that condition A is open would then imply that the values $F(\hat{v})$ are uniquely determined for all unit-length $\hat{v}$ in an open cone. But that implies that the coefficients of F are uniquely determined. Hence $\partial_n g^{\alpha\beta}(x_0)$ and $\partial_n \zeta_\alpha(x_0)$ would be uniquely determined. By again appealing to the fact that condition A is open in ∂SM , we could conclude that $\partial_n g^{\alpha\beta}$ and $\partial_n \zeta_\alpha$ are in fact uniquely determined in a neighborhood of x_0 in ∂M .

To show that $F(\hat{v}_0)$ is uniquely determined, we consider the right side of (2.7) at $x = x_0$ as $m \rightarrow \infty$. In the second term, $\partial_n \zeta_n$ is independent of m and

$$(2.8) \quad \partial_n^2 \rho_m(x_0) = \partial_n^2 \rho(x_0, y_{s_m}) \rightarrow \partial_n^2 \rho(x_0, y_*).$$

Since $(\hat{v}_{s_m})_n = \sin(s_m) \rightarrow 0$, we conclude that the limit of the second term is 0:

$$(2.9) \quad 2(\hat{v}_{s_m})_n(\partial_n \zeta_n - \partial_n^2 \rho_{s_m}) \rightarrow 0.$$

It only remains to show that the limit of the first term of the righthand side is uniquely determined at x_0 . For each m , $\partial_n \rho_m(x)$ is known in $\mathcal{H}_m$. Hence $\partial_n \partial_\alpha \rho_m = \partial_\alpha \partial_n \rho_m$ is also known in $\mathcal{H}_m$ and in particular at x_0 and in the limit $m \rightarrow \infty$. Thus, $\partial_n g^{\alpha\beta}$ and $\partial_n \zeta_\alpha$ are uniquely determined for $x \in \partial M$ near x_0 .

Before calculating higher derivatives, we return to equation (2.7). All coefficients except those in the far right hand term are known in $x \in \mathcal{H}_m$. Therefore, by solving the equation, we find that $\partial_n \zeta_n - \partial_n^2 \rho_{s_m}$ is determined in the same set. $\partial_n \zeta_n$ is known because ζ_n is known in a neighborhood of ∂M . So we find that $\partial_n^2 \rho_{s_m}(x)$ is also determined in $\mathcal{H}_m$. Hence all coefficients of (2.7) are in fact uniquely determined in $\mathcal{H}_m$.

To recover higher order normal derivatives of g and ζ , we continue this process, applying ∂_n to equation (2.6) to obtain

$$(2.10) \quad \begin{aligned} & (\partial_n^2 g^{\alpha\beta})(\hat{v}_{s_m})_\alpha (\hat{v}_{s_m})_\beta + 4(\partial_n g^{\alpha\beta}) \partial_n (\hat{v}_{s_m})_\alpha (\hat{v}_{s_m})_\beta + \\ & 2g^{\alpha\beta} (\partial_n^2 \zeta_\alpha - \partial_n^2 \partial_\alpha \rho_m) (\hat{v}_{s_m})_\beta + 2g^{\alpha\beta} \partial_n (\hat{v}_{s_m})_\alpha \partial_n (\hat{v}_{s_m})_\beta + \\ & 2(\partial_n (\hat{v}_{s_m})_n)^2 + 2(\hat{v}_{s_m})_n (\partial_n^2 \zeta_n - \partial_n^3 \rho_m) = 0. \end{aligned}$$

The second, fourth, and fifth terms in this sum have already been shown to be determined in $\mathcal{H}_m$. Therefore, so is the combined sum of the other terms:

$$\begin{aligned} & \partial_n^2 g^{\alpha\beta} (\hat{v}_{s_m})_\alpha (\hat{v}_{s_m})_\beta + 2g^{\alpha\beta} (\partial_n^2 \zeta_\alpha - \partial_n^2 \partial_\alpha \rho_m) (\hat{v}_{s_m})_\beta \\ & + 2(\hat{v}_{s_m})_n (\partial_n^2 \zeta_n - \partial_n^3 \rho_m). \end{aligned}$$

We have already shown that $\partial_n^2 \rho_m$ is determined in $\mathcal{H}_m$. Therefore, by differentiation, so is $\partial_n^2 \partial_\alpha \rho_m$. By arguments similar to those of (2.8) and (2.9), we find that at x_0 , as $m \rightarrow \infty$,

$$2(\hat{v}_{s_m})_n (\partial_n^2 \zeta_n - \partial_n^3 \rho_m) \rightarrow 0.$$

Therefore, we find that the following quantity is determined at x_0 :

$$\partial_n^2 g^{\alpha\beta} (\hat{v}_0)_\alpha (\hat{v}_0)_\beta + (2g^{\alpha\beta} \partial_n^2 \zeta_\alpha) (\hat{v}_0)_\beta.$$

As in the previous iteration, we regard this expression as a quadratic function in v . By appealing to the open nature of condition A, we find that the coefficients must be uniquely determined. This is true at x_0 , but again since condition A is open, it is also true in a neighborhood of x_0 . Hence $\partial_n^2 g^{\alpha\beta}$ and $\partial_n^2 \theta_\alpha$ are uniquely determined on the boundary near x_0 .

Returning to equation (2.10), we now find that all the remaining unknown terms are in fact uniquely determined in $\mathcal{H}_m$. In particular, since $\partial_n^2 \zeta_n$ was already uniquely determined by lemma 2, $\partial_n^3 \rho_m$ must be determined in $\mathcal{H}_m$.

To determine the higher order derivatives, we successively apply ∂_n to equation (2.10). At each stage, after discarding all terms with coefficients that are known in $\mathcal{H}_m$, we obtain

$$\begin{aligned} \partial_n^k g^{\alpha\beta} (\hat{v}_{s_m})_\alpha (\hat{v}_{s_m})_\beta + 2g^{\alpha\beta} (\partial_n^k \zeta_\alpha - \partial_n^k \partial_\alpha \rho_m) (\hat{v}_{s_m})_\beta \\ + 2(\hat{v}_{s_m})_n (\partial_n^k \zeta_n - \partial_n^{k+1} \rho_m). \end{aligned}$$

Following (2.8) and (2.9), we find that at x_0 the third term goes to zero as $m \rightarrow \infty$. From the last step in the previous iteration, $\partial_n^k \rho_m$ is known in $\mathcal{H}_m$. Therefore, by differentiation, $\partial_n^k \partial_\alpha \rho_m$ is known at x_0 in the limit as $m \rightarrow \infty$. The remaining two terms are then regarded as a quadratic function in $\hat{v}$ and the coefficients $\partial_n^k g^{\alpha\beta}$ and $\partial_n^k \zeta_\alpha$ are recovered as in the previous iterations. This allows us to go back and determine the coefficients of the third term including $\partial_n^{k+1} \rho_m$. Hence we find that the full jets of g and ζ are completely determined at x_0 and even in some small neighborhood about x_0 . Since $\Omega = d\zeta$, the same is true for the jet of Ω .

The assumption that $w_* \neq v_0$ was used implicitly in (2.8). In the case that $w_* = v_0$, the argument falls apart because the length of the curve approaches 0 as $s \rightarrow 0$ and, consequently, $\partial_n^2 \rho(x_0, y_{s_m})$ is not uniformly bounded with respect to m . Hence (2.9) does not necessarily hold and the quadratic function $F(\hat{v})$ cannot be isolated.

Case II: $w_* = v_0$

Lemma 4. *For $s \geq 0$ sufficiently small, $\rho(x_0, y_s)$ is uniquely determined by the scattering data.*

Proof. Recall, for small s , y_s is the first intersection of γ_{v_s} with ∂M . Let J be a small interval $(0, \delta)$. We shall show that if δ is sufficiently small, then y_s is a smooth curve in ∂M for $s \in J$. This will hold for example if ∂M is strictly convex with respect to magnetic geodesics in the direction of v_0 . Strict convexity holds when

$$(2.11) \quad II_{x_0}(v_0) - Y(x_0)v_0$$

is positive, where II denotes the second fundamental form of ∂M with respect to g , and Y denotes the $(1,1)$ -tensor determined by the magnetic field. However, strict convexity is not necessary. By Taylor's formula, it suffices to show that the first nonzero derivative of (2.11) in the direction of v_0 is positive. Note that non-trapping and analyticity preclude the possibility that all derivatives be zero, for analytic continuation would then imply that the magnetic geodesic γ_{v_0} is trapped in ∂M . If the first nonzero derivative of (2.11) were negative, then the travel time necessary to reach y_s from x_0 would be bounded from below. Hence it would be impossible for a sequence (y_s, w_s) to approach (x_0, v_0) as $s \rightarrow 0$ without γ_{v_0} being trapped.

We conclude that y_s is a smooth curve in ∂M for $s \in J$. Therefore, $\rho(x_0, y_s)$ is a smooth function on J . By equation (2.2),

$$\frac{d}{ds} \rho(x_0, y_s) = \langle w_s, \partial_s y_s \rangle_g - \langle \zeta_{y_s}, \partial_s y_s \rangle,$$

where w_s is the vector tangent to γ_{v_s} at y_s . All terms on the right side are determined by the scattering data, therefore, by integration, $\rho(x_0, y_s)$ is determined up

to a constant. By continuity at $s = 0$, we find that the constant must be 0, since $\lim_{s \rightarrow 0} \rho(x_0, y_s) = 0$. $\square$

On M'_i for $i = 1, 2$, consider the quadratic function $F_i(x)v = |v|_{g_i}^2 - \langle \zeta_i(x), v \rangle$. Omitting the subscript i , in boundary normal coordinates F_i takes the form:

$$F_i(x)v = g_{\alpha\beta}(x)v^\alpha v^\beta + (v^n)^2 - \zeta_\alpha(x)v^\alpha - \zeta_n(x)v^n.$$

(g_1, ζ_1) and (g_2, ζ_2) have the same jet at x_0 if and only if

$$(2.12) \quad \partial_n^k F_1(x_0)v = \partial_n^k F_2(x_0)v$$

for all $k > 0$ and all v in a small conic neighborhood of v_0 in $S_{x_0}\partial M$.

Suppose equation (2.12) fails for some $v_1 \in S_{x_0}\partial M$ close to v_0 . Then by considering the Taylor expansion, there exists a neighborhood of (x_0, v) for which $F_1(x)v > F_2(x)v$ for all x with $x^n > 0$. Let $(\gamma_{v_s})_i$ denote the magnetic geodesic in M'_i with initial vector $v_s = \cos(s)v_1 + \sin(s)\partial_n$. Then we have

$$\begin{aligned} \rho_1(x_0, y_s) &= \int_{(\gamma_{v_s})_1} F_1(x)v > \int_{(\gamma_{v_s})_1} F_2(x)v \geq \\ &\int_{(\gamma_{v_s})_2} F_2(x)v = \rho_2(x_0, y_s). \end{aligned}$$

The second inequality follows from the fact that $(\gamma_{v_s})_2$ is a minimizing curve for the action functional defined by F_2 . This contradicts the fact that $\rho_1(x_0, y_s) = \rho_2(x_0, y_s)$. $\square$

Remark : The analytic assumption was only used in Case II and only to establish a weak convexity condition. Therefore, this theorem may be applied to nonanalytic systems where that condition is added to the hypothesis.

2.5. Recovering the magnetic system in a band about ∂M . The mapping $\varphi_0 : V_1 \rightarrow V_2$ given by (1.2) is a magnetic equivalence if (g_1, Ω_1) and (g_2, Ω_2) have the same coefficients when expressed in their respective boundary normal coordinates. By Theorem 2 and condition A on the first magnetic system, the respective coefficients have the same jets at least at one point in each component of ∂M . By analytic continuation the coefficients must be equal on all of $\partial M \times (-\epsilon, \epsilon)$. We conclude $\varphi_0^* g_2 = g_1$ and $\varphi_0^* \Omega_2 = \Omega_1$.

3. THEOREM 3: RECOVERY OF THE TRAVEL TIME DATA

3.1. Jacobi fields and conjugate points. Given a magnetic geodesic $\gamma : [0, T] \rightarrow M$, let $\mathcal{A}$ be the operator on smooth vector fields Z along γ defined by

$$\mathcal{A}(Z) = Z'' + R(\gamma', Z)\gamma' - Y(Z') - (\nabla_Z Y)(\gamma').$$

A vector field J along γ is said to be a *magnetic Jacobi field* if it satisfies the equations

$$(3.1) \quad \mathcal{A}(J) = 0$$

and

$$(3.2) \quad \langle J', \gamma' \rangle = 0.$$

A magnetic Jacobi field along a magnetic geodesic γ is uniquely determined by specifying J and J' at a point. To see this, consider the orthonormal basis defined by extending an orthonormal basis $e_1, \dots, e_n$ at $\gamma(0)$ by requiring that

$$(3.3) \quad e'_i = Y(e_i)$$

along γ . This extension gives an orthonormal basis at each point since

$$\frac{d}{dt} \langle e_i, e_j \rangle = \langle Y(e_i), e_j \rangle + \langle e_i, Y(e_j) \rangle = 0.$$

Using this basis, $J = \sum f_i e_i$ and we can write equation 3.1 as the system

$$f''_j + \sum_{i=1}^n f'_i y_{ij} + \sum_{i=1}^n f_i a_{ij} = 0$$

where $y_{ij} = \langle Y(e_i), e_j \rangle$ and

$$a_{ij} = \langle \nabla_{\gamma'} Y(e_i) + R(\gamma', e_i) \gamma' - Y(Y(e_i)) - (\nabla_{e_i} Y)(\gamma'), e_j \rangle.$$

This is a linear second order system, and therefore it has a unique solution for each set of initial conditions. Moreover, since the metric and magnetic fields are analytic, so will be the solutions.

It is easy to see from the definition that γ' is always a magnetic Jacobi field. Unlike the case of straight geodesics, this is the only magnetic Jacobi field parallel to γ' . Another difference from the straight geodesic case is that magnetic Jacobi fields that are perpendicular to γ' at $t = 0$ do not stay perpendicular for all t . For this reason we will sometimes consider instead the orthogonal projection $J^\perp = J - f\gamma'$ where $f = \langle J, \gamma' \rangle$. The parallel component $f\gamma'$ is uniquely determined by $J^\perp$ and $J(0)$ since

$$f' = \langle J', \gamma' \rangle + \langle J, \gamma'' \rangle = \langle J, Y(\gamma') \rangle = \langle J^\perp, Y(\gamma') \rangle.$$

Magnetic Jacobi fields are the variational fields corresponding to variations through magnetic geodesics. This can be seen by considering the variation

$$f(t, s) = \gamma_s(t) = \exp_{\tau(s)}^\mu(t\theta(s))$$

where $\tau(s)$ is any curve with $\tau'(0) = J(0)$ and $\theta(s)$ is a vector field along τ with $\theta(0) = \gamma'(0)$ and $\theta'(0) = J'(0)$. It is a straight forward computation to check that the variational field $\frac{\partial f}{\partial s}(t, 0)$ is a magnetic Jacobi field (see [He]).

There is a close relation between magnetic Jacobi fields and conjugate points, analogous to the straight geodesic case. This can be summarized in the following Proposition, proved in [He].

Proposition 3.1. *Let $\gamma_\theta : [0, T] \rightarrow M$ be the magnetic geodesic with $\gamma(0) = x$. The point $p = \gamma(t_0)$ is conjugate to x along γ if and only if there exist a magnetic Jacobi field J along γ , not identically zero, with $J(0) = 0$ and $J(t_0)$ parallel to γ' .*

Moreover, the multiplicity of p as a conjugate point is equal to the number of linearly independent such Jacobi fields.

3.2. Proof of Theorem 3. Consider magnetic geodesics $\gamma_1 : [0, T_1] \rightarrow M_1$ and $\gamma_2 : [0, T_2] \rightarrow M_2$ that satisfy condition B and such that $\gamma_2(t) = \varphi_0(\gamma_1(t))$ for small t . Suppose, moreover, that γ_1 is never tangent to ∂M_1 . Since both systems have the same scattering data they must exit the manifold at corresponding points and directions, that is $\gamma_2(T_2) = \varphi_0(\gamma_1(T_1))$ and $\gamma_2'(T_2) = \varphi_{0*}(\gamma_1'(T_1))$. We will call such geodesics correspondent, and, through φ_0 , shall implicitly identify $\gamma_1(0)$ to $\gamma_2(0)$ as well as their neighborhoods and tangent spaces.

We want to compare variations of γ_1 and γ_2 by defining for a variation

$$f_1(t, s) = \exp_{\tau(s)}^\mu(t\theta(s))$$

of γ_1 a corresponding variation

$$f_2(t, s) = \exp_{\varphi_0(\tau(s))}^\mu(t\tilde{\varphi}_0(\theta(s)))$$

of γ_2 . Nonetheless, $f_1(T_1, s)$ will be in V for small s and that is enough for our purpose. Therefore $f_1(T_1, s) = f_2(T(s), s)$ where $T(s) : (-\epsilon, \epsilon) \rightarrow \mathbb{R}$ is differentiable with $T(0) = T_2$. By taking derivatives with respect to s we see that

$$\frac{\partial f_1}{\partial s}(T_1, 0) = \frac{\partial f_2}{\partial s}(T_2, 0) + T'(0)\gamma_2'(T_2),$$

so corresponding Jacobi fields agree at their endpoints up to a term tangent to γ_i' .

We want to consider all Jacobi fields along γ_1 with $J(T_1) = 0$. For this we define the magnetic Jacobi tensor $\mathcal{J}_1$ with the initial conditions $\mathcal{J}_1(T_1) = 0$ and $\mathcal{J}_1'(T_1) = Id$. This is a $(1, 1)$ tensor in the space of vectors orthogonal to γ_1' . For any vector η at $\gamma_1(T_1)$ perpendicular to γ_1' , the vector field $J^\perp(t) = \mathcal{J}_1(\eta)(t)$ is the perpendicular part of the Jacobi field with $J(0) = 0$ and $J'(0) = \eta$.

Correspondingly, define the magnetic Jacobi tensor $\mathcal{J}_2$ with $\mathcal{J}_2(T_2) = 0$ and $\mathcal{J}_2'(T_2) = Id$. Since correspondent Jacobi fields agree at their endpoints, up to a parallel component, so will the corresponding Jacobi tensors. Therefore $\mathcal{J}_1(t) = \mathcal{J}_2(t)$ for small t . Moreover, this is an analytic function and we can use analytic continuation to see that they must agree for all t , as long as both are well defined.

Assume, without loss of generality, that $T_1 < T_2$. Then, $\mathcal{J}_1(t) = \mathcal{J}_2(t)$ for $0 \leq t \leq T_1$. In particular, at T_1 we have $\mathcal{J}_2(T_1) = \mathcal{J}_1(T_1) = 0$. which would imply that $\gamma_2(T_1)$ is conjugate to $\gamma_2(T_2)$, of order $n - 1$. Since γ_1 satisfies condition B this can't be the case, therefore $T_2 = T_1$.

To see that the length of all magnetic geodesics agree, note that magnetic geodesics that are tangent to ∂M form the boundary of $\mathcal{G}$. In particular they are limit points, and form a set of measure 0. Therefore, we know that the lengths of γ_1 and γ_2 agree for a dense subset of $\mathcal{G}_1$. The length of geodesics is a continuous function on $\mathcal{G}$, so the difference in lengths is also a continuous function that is 0 in a dense subset. This implies that the lengths agree for all magnetic geodesics.

3.3. About the necessity of condition B. In the presence of conjugate points of order $n - 1$ the proof above would say that the lengths may differ by the distance between conjugate points of such order. and that $\mathcal{J}_2(T_1 - s) = \mathcal{J}_1(T_1 - s) = \psi \circ \mathcal{J}_2(T_2 - s)$, where ψ is a local isometry of TM_2 allowing the possibility that the diffeomorphism $\tilde{\varphi}_0$ does not extend in a compatible way through γ_1 and γ_2 . So $\mathcal{J}_2$ has a period, up to isometry, of length $T_2 - T_1$.

FIGURE 1.

In the case of straight geodesics ($\Omega = 0$) we can see this behavior by looking at the following examples.

Let M_1 be an analytic subset of the sphere S^2 that contains the southern hemisphere. Let M_2 be a region of $\mathbb{R}P^2$ with the same boundary. We can see it as removing the southern hemisphere from M_1 and identifying antipodal points in the equator (See figure 1). This manifolds have the same scattering data but any geodesic in M_1 that passes through the southern hemisphere will be longer by π than the corresponding geodesic in M_2 .

Another similar example is when N_1 is a subset of the sphere S^2 that contains both poles and a meridian τ . To build N_2 we cut open along τ and glue another S^2 opened at the meridian in such a way that whenever you cross τ you move from one sphere to the other (see figure 2). These manifolds have the same scattering data but any geodesic in N_1 that passes through τ will be shorter by 2π than the corresponding geodesic in N_2 . This is not a Riemannian manifold, since the poles are singular points. But it is orientable and the Jacobi tensors will be periodic with a period of 2π .

The need of condition B is clear in the examples above, where we can see that the presence of a conjugate point of order $n - 1$ allows the length of a geodesic to change. The question remains if it is necessary as an independent hypothesis. It seems to be that, like in the examples above, conjugate points of order $n - 1$ only appear when there are trapped geodesics. If this is true, it would make condition B empty in this setting.

4. THEOREM 4: CONSTRUCTION OF THE MAGNETIC EQUIVALENCE

We have two non-trapping, analytic magnetic systems (M_i, g_i, Ω_i) with the same scattering data and travel time data. Moreover, the mapping $\varphi_0 : V_1 \rightarrow V_2$ is a magnetic equivalence. To prove Theorem 4, we must extend φ_0 to a magnetic equivalence $\varphi : M'_1 \rightarrow M'_2$.

This has been done in the absence of magnetic fields in [V]. The proof carries over in the presence of magnetic fields with only changes in notation. Therefore, we shall only sketch the proof here.

4.1. Extension of φ_0 to M'_1 .

FIGURE 2.

Proof. First we define a mapping $\tilde{\varphi} : SM_1 \rightarrow M_2$. We then show that all vectors lying over the same base point in M_1 map to the same point in M_2 , and that the induced map $\varphi : M_1 \rightarrow M_2$ agrees with φ_0 on their common domain.

Let $(x, \theta) \in SM_1$, and consider the magnetic geodesic $\gamma_{x,\theta}(t)$. Going backwards along $\gamma_{x,\theta}$, we will eventually leave M_1 by the non-trapping assumption. We define

$$T_0 = T_0(x, \theta) = \inf\{t \geq 0 : \gamma(x, \theta)(-t) \notin M_1\}.$$

$T_0 \geq 0$ satisfies $\gamma_{x,\theta}(-T_0) \in \partial M$. Moreover, by the fact that ∂M is analytic, it is not hard to see that $\gamma_{x,\theta}(-T_0 - s) \in V_1 \setminus M_1$ for all s such that $0 < s < \delta$ for some sufficiently small $\delta = \delta(x, \theta)$. We arbitrarily choose

$$-T = -T(x, \theta) \in (-T_0 - \delta, -T_0),$$

and let $(z_{x,\theta}, \xi_{x,\theta}) \in SM'_1$ be given by

$$(z_{x,\theta}, \xi_{x,\theta}) = (\gamma_{x,\theta}(-T), \gamma'_{x,\theta}(-T)).$$

Let $(y_{x,\theta}, \eta_{x,\theta}) \in SM'_2$ be its image by φ_0 ,

$$(y_{x,\theta}, \eta_{x,\theta}) = \varphi_{0*}(z_{x,\theta}, \xi_{x,\theta}).$$

Define

$$\tilde{\varphi}(x, \theta) = \gamma_{y_{x,\theta}, \eta_{x,\theta}}(T).$$

Proposition 2. $\tilde{\varphi}$ is a well defined function on SM_1 with values in M_2 .

Proof. It must be shown that the value of $\tilde{\varphi}(x, \theta)$ is independent of the choice of $T \in (-T_0 - \delta, -T_0)$, and that the values do belong to M_2 . The first statement follows from the fact that the two magnetic systems are equivalent via φ_0 in V . The second follows from the fact that the two systems have share the same length data. See [V] for details. $\square$

Proposition 3. The value of $\tilde{\varphi}(x, \theta)$ is independent of the direction θ .

Lemma 5. Let M' be an open manifold with analytic metric g . Then for every $x_0 \in M'$, there exists a positive number r such that the squared distance function is analytic on the set

$$\Delta_r(x_0) = \{(x, y) : d(x, x_0) < r, d(x, y) < r\}.$$

If K is a compact set contained within the interior of M' , then there is an open $O \subset M'$ containing K and a positive number r such that the squared distance function is analytic on the set

$$\Delta_{O,r}(K) = \{(x, y) : x \in O, d(x, y) < r\}.$$

See [V] for proof.

Proof. Since the sphere $|\theta|_g = 1$ is connected, it is sufficient to show that for fixed x , $\tilde{\varphi}(x, \theta)$ is locally constant in θ .

Fix (x_0, θ_0) , and let $N \subset S_{x_0}M_1$ be a neighborhood of θ_0 . Let (z_0, ξ_0) and (y_0, η_0) correspond to (x_0, θ_0) following the notation above. Then we have

$$\begin{aligned} x_0 &= \gamma_{z_0, \xi_0}(T) \\ \tilde{\varphi}(x_0, \theta_0) &= \gamma_{y_0, \eta_0}(T). \end{aligned}$$

For all $\theta \in N$, let $(z, \xi) = (\gamma_{x_0, \theta}(-T), \gamma'_{x_0, \theta}(-T))$, so that

$$x_0 = \gamma_{z, \xi}(T).$$

Let $(y, \eta) = \varphi_{0*}(z, \xi)$. It can be shown that if N is sufficiently small,

$$(4.1) \quad \tilde{\varphi}(x_0, \theta) = \gamma_{y, \eta}(T).$$

Equation (4.1) seems to be a direct application of the definition of $\tilde{\varphi}$ but in fact, between x_0 and z , the curve $\gamma_{x_0, \theta}$ can pass across the boundary in and out of M_1 . Therefore, T is not necessarily a valid choice for $T(x_0, \theta)$ according to the definition. Nevertheless, using the fact that the two magnetic systems have the same scattering and length data, equation (4.1) still holds.

According to lemma 5, the functions

$$\begin{aligned} \rho_1(t) &= d_{g_1}^2(\gamma_{z_0, \xi_0}(t), \gamma_{z, \xi}(t)), \quad \text{and} \\ \rho_2(t) &= d_{g_2}^2(\gamma_{y_0, \eta_0}(t), \gamma_{y, \eta}(t)) \end{aligned}$$

will be analytic wherever their values are less than some fixed constant r .

Since φ_0 is a magnetic equivalence, it carries magnetic geodesics into magnetic geodesics. $(y, \eta) = \varphi_{0*}(z, \xi)$. Therefore, for t near 0, we have

$$\varphi_0(\gamma_{z, \xi}(t)) = \gamma_{y, \eta}(t).$$

A magnetic equivalence is, in particular, an isometry of metrics, so we conclude that for t near 0, $\rho_1(t) = \rho_2(t)$. By analytic continuation, the two function must be equal for all t up to T . Therefore, $\rho_2(T) = \rho_1(T) = 0$. This implies that

$$\tilde{\varphi}(x_0, \theta) = \gamma_{y, \eta}(T) = \gamma_{y_0, \eta_0}(T) = \tilde{\varphi}(x_0, \theta_0).$$

□

We define $\varphi : M'_1 \rightarrow M'_2$ by

$$\begin{aligned} x &\mapsto \tilde{\varphi}(x, \theta), & \text{for } x \in M_1 \\ x &\mapsto \varphi_0(x), & \text{for } x \in M'_1 \setminus M_1. \end{aligned}$$

The magnetic geodesic flows on the respective sphere bundles of M_1 and M_2 are analytic. This implies that φ is an analytic mapping. The fact that $\varphi|_{V_1} = \varphi_0$ follows directly from the definition of φ and the fact that φ_0 is a magnetic equivalence. By analytic continuation, φ must satisfy

$$\varphi^* g_2 = g_1, \quad \varphi^* \Omega_2 = \Omega_1.$$
